CHAPTER 1

INTRODUCTION

This Addendum has been necessary due to the delays in analysis of pesticide residues in soil, water and food samples for reasons outlined in Chapter 1.4 of the Main Report. The results of the analyses and the conclusions drawn regarding hazard to man, livestock and the environment from pesticides applied by air to cotton are now discussed in Chapter 2. The opportunity has also been taken to comment on aspects of the Integrated Pest Management concept and its implications for the Gezira and other production Boards, and to make a few suggestions on research work necessary for implementation of such a pest control policy. The programme proposed by ARC Cotton Research Coordinator for 1986-87 season (Ref. 1) has been taken into consideration here. Discussions were also held with the British ODA mission on a cotton pesticide research project that visited the Gezira in 1985 and early 1986.

CHAPTER 2

ASSESSMENT OF ENVIRONMENTAL HAZARD

2.1 INSECTICIDE DRIFT DOWNWIND

2.1.1 General

The subject has been discussed in detail in Chapter 8 of the Main Report and in its Annex A, Part 1. Fifteen spray drift studies were carried out. Results from eight on the Gezira were included in the main report, and those from six on other schemes are given here. Table 2.1, taken from Table AA.4 of the Annex summarises climate conditions and droplet distribution. One trial failed due to mechanical faults in application. Data on methodology for all studies are given in the main report. Interpretation of results for the six studies now reported can only be made as direct assessment of the quantitative g.l.c. analyses. The detailed droplet analyses, which in eight of the studies permitted interpretation of g.l.c. analysis as percentage recoveries of the amounts applied, could not be made for these six studies. In these basic monitoring studies it was not planned to place MgO_2 coated slides in the field, nor were rotating MgO tubes placed adjacent to the acrylic wool collectors, and direct correlation between g.l.c. analysis and field application was outside the scope of the basic monitoring programme.

The results of g.l.c. analyses are shown in graphical form in Figures 2.1 to 2.6 and in Table 2.2. The original data are given as Appendix A. In the Figures the axis showing the amounts of insecticide recovered (μg/m of wool collector) is shown as bands scaled at 1:1, 1:4, 1:17.5 and 1:90 ratios. This has been necessary to permit presentation of non-transformed data which has a wide spread. (It could be transformed to the square-root or logarithm if so desired, e.g. for statistical analysis). As indicated in Table 2.2 wool collectors were placed on the field borders, along the edge of the effective spray-swath of the aircraft, in five of the trials. The amounts of insecticide recovered from these collectors is arguably representative of the amounts that were applied in practice at the downwind edge of the field, assuming cross-field drift to compensate for loss of downwind drift from the field-edge swath. Table 2.3 shows downwind deposition of insecticide as a percentage of field-edge recovery.

2.1.2 Discussion of Results

The amounts of insecticide recovered at 500 - 600 m downwind in these studies were of a similar order of magnitude as in the eight Gezira studies (Table AA.3, Main Report Annex). The amounts recovered by the field-edge collectors were substantially below the estimations for in-field collection for the Gezira trials for the five insecticides represented in both groups of trials, indicating that the method for estimation of in-field deposit is reasonably accurate (Annex A, para. 1.3.1) since it would be expected that in-field levels would be greater than field edges.

The conclusions reached in the Main Report are supported by the additional data generated by the six studies carried out at Rahad, New Halfa and White Nile. Maximum fallout of chemical occurred within 100 m of the field except in the cases of studies 12 and 15. In 12 no sharp decline was noted but by 300 m downwind recovery levels were low. In this ULV study abnormally large droplets were collected on the in-field sensitive papers (Figure AA.13, Survey 4, Study 12) and it is possible this resulted in fewer but relatively larger involatile droplets and thus amounts of chemical, drifting downwind. The results from study 15 are suspect. There is no reason for the rise in recovery levels of both

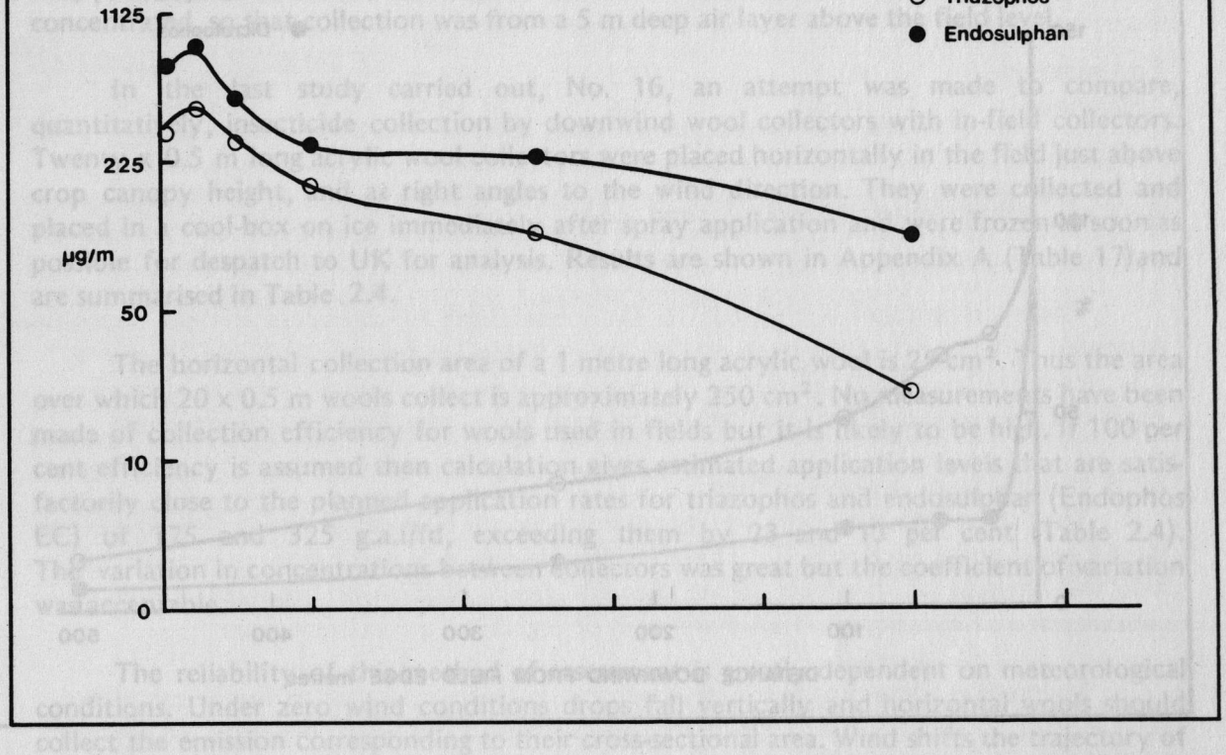

FIGURE 2.6 Study 19 (11.12.1985)

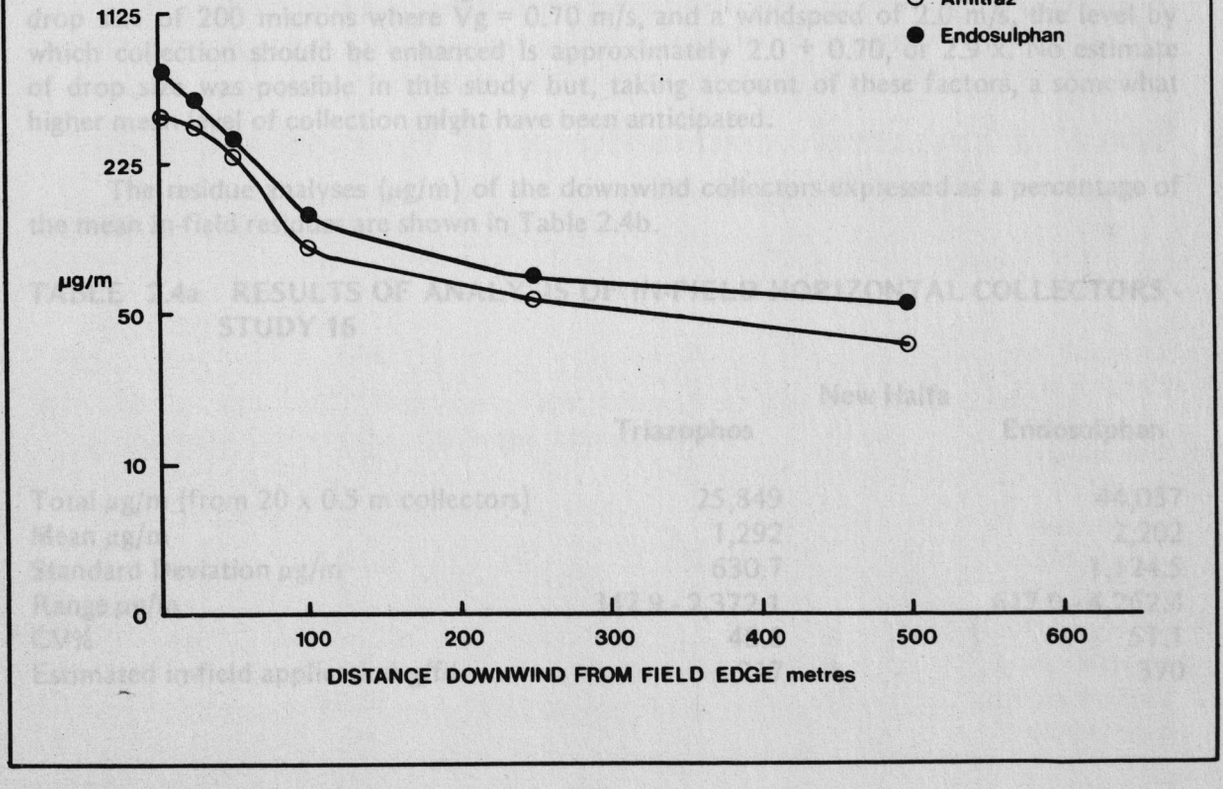

FIGURE 2.7 STUDY 18 (4.11.85)
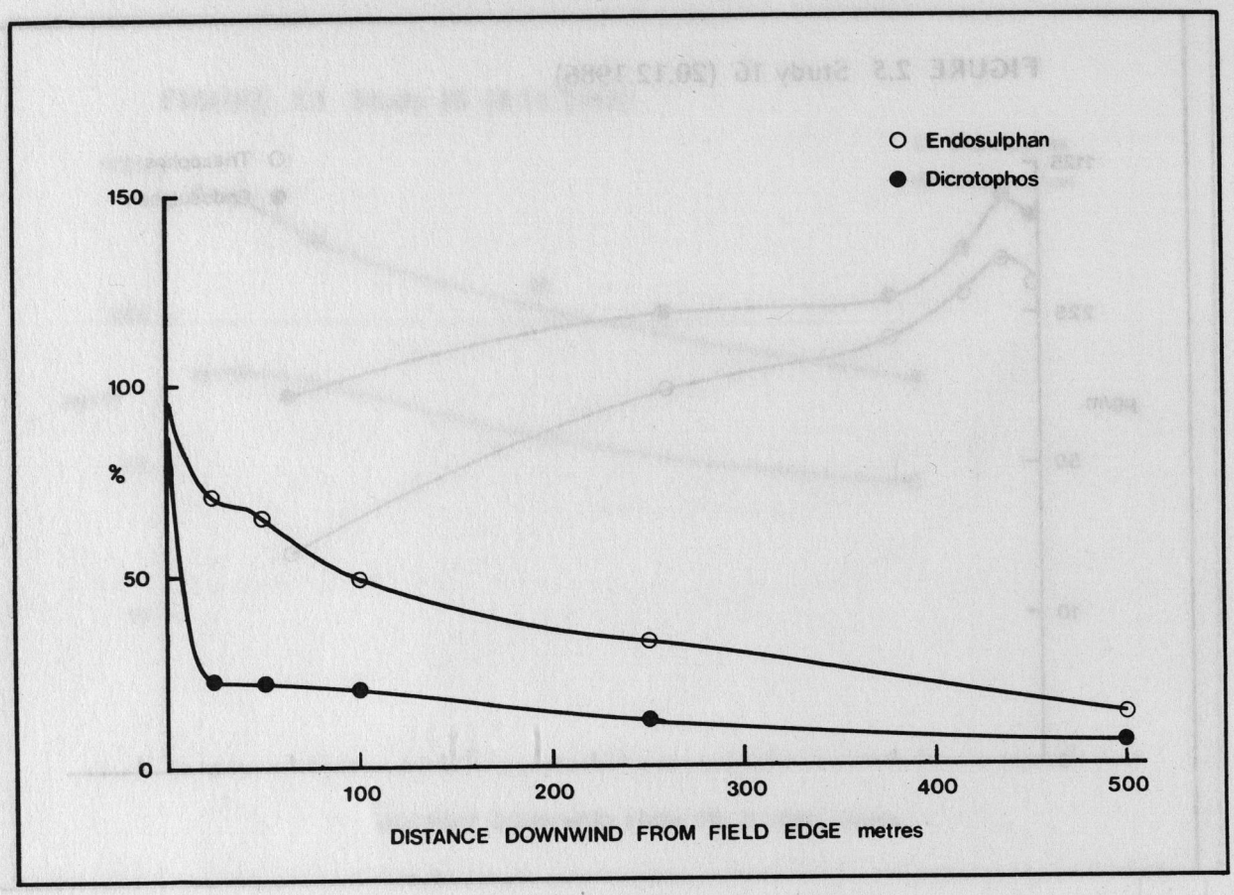
Downwind insecticide drift as % of mean in-field deposition for one metre long vertically disposed wool strand collectors.



dicrotophos and endosulphan from 200 m downwind other than contamination during collection of the wool samplers from the field, since conditions for spraying appeared reasonably good and no abnormalities were noted in application. In study 11 the 600 m collectors were situated on top of a canal bank and recovery of insecticide showed a slight rise, presumably due to upward movement of the airflow, whereby drifting droplets were concentrated, so that collection was from a 5 m deep air layer above the field level.

In the last study carried out, No. 16, an attempt was made to compare, quantitatively, insecticide collection by downwind wool collectors with in-field collectors. Twenty x 0.5 m long acrylic wool collectors were placed horizontally in the field just above crop canopy height, and at right angles to the wind direction. They were collected and placed in a cool-box on ice immediately after spray application and were frozen as soon as possible for despatch to UK for analysis. Results are shown in Appendix A (Table 17)and are summarised in Table 2.4.

The horizontal collection area of a 1 metre long acrylic wool is 25 cm^2. Thus the area over which 20 x 0.5 m wools collect is approximately 250 cm^2. No measurements have been made of collection efficiency for wools used in fields but it is likely to be high. If 100 per cent efficiency is assumed then calculation gives estimated application levels that are satisfactorily close to the planned application rates for triazophos and endosulphan (Endophos EC) of 175 and 325 g.a.i/fd, exceeding them by 23 and 13 per cent (Table 2.4). The variation in concentrations between collectors was great but the coefficient of variation was acceptable.

The reliability of this method of assessment is greatly dependent on meteorological conditions. Under zero wind conditions drops fall vertically and horizontal wools should collect the emission corresponding to their cross-sectional area. Wind shifts the trajectory of the drops out of the vertical so that the wools collect an enhanced fraction of the emission computed from their cross-sectional area. The stronger the wind the greater the increase in drops collected. This enhanced fraction may be roughly calculated from the mean wind speed, $\bar{u}$, divided by the terminal velocity of the drops, $\bar{V}g$. For example with an 'average' drop size of 200 microns where $\bar{V}g = 0.70$ m/s, and a windspeed of 2.0 m/s, the level by which collection should be enhanced is approximately 2.0 ÷ 0.70, or 2.9 x. No estimate of drop size was possible in this study but, taking account of these factors, a somewhat higher mean level of collection might have been anticipated.

The residue analyses (µg/m) of the downwind collectors expressed as a percentage of the mean in-field residues are shown in Table 2.4b.

TABLE 2.4a RESULTS OF ANALYSIS OF IN-FIELD HORIZONTAL COLLECTORS - STUDY 16

TABLE 2.4b DOWNWIND DEPOSITION AS A % OF IN-FIELD DEPOSITION ON ACRYLIC WOOL COLLECTORS (μg/m) - STUDY 16[1]

	Distance Downwind (m)				
	25	50	100	250	500
Endosulphan	42.1	27.5	14.5	11.2	6.2
Triazophos	46.4	26.6	15.5	11.1	5.4

Note: [1] *Data derived from Table 2.2 and 2.4a*

These percentages are similar to the percentages of estimated in-field deposition presented in Table 8.1 of the main report, and of field-edge recovery in Table 2.4 above. It is therefore concluded that the use of acrylic wool collectors gives a reliable method of assessing downwind drift and that the conclusions drawn regarding hazards are sound.

2.1.3 Hazards from Downwind Drift

The factors affecting drift and its potential hazard to man have been discussed in the Main Report under Section 8.1.3. The principle conclusion is that hazard is minimal and that the chances of ill-effects either through direct contact or indirectly through consumption of contaminated sorghum grain or vegetables are extremely small.

Theoretical contamination levels assuming worse case parameters can be calculated for sorghum grain crops, based on the recoveries from acrylic wool collectors. An average sorghum head in vertical plane occupies approximately 75 cm^2 and may have an average head weight of about 27 grams (mean of 14 varieties reported by Sudan workers). Impact and retention of small drifting droplets by a solid object as a sorghum head is low, due to diversion of the moving airstream. If however a high efficiency is assumed (worst case hypothesis) then a sorghum head would collect three times the amount of insecticide of a one metre long wool strand. Theoretical contamination levels have been calculated on this basis for 250 and 500 m distances and are shown in Table 2.5.

TABLE 2.5 THEORETICAL CONTAMINATION LEVELS OF SORGHUM HEADS BEFORE HARVEST - ppm

Insecticide	No. Studies	250 m	500 m
Endosulphan	8	25.1	14.1

Amitraz	2	15.0	5.6
Alphamethrin	1	0.7	0.3
Cypermethrin	2	2.1	1.0
Deltamethrin	1	0.03	0.01
Fenvalerate	1	4.1	2.3

Fields (Numbers) on the Gezira are 280 m wide. Sorghum may be in the adjacent number or the second, occasionally third, number away. Harvest is in the second half of November so that head contamination from four to six sprays is possible. In order to assess whether this level of field contamination might be potentially hazardous to the farmer consumer samples of heads were taken just before harvest and of grain from farm stores approximately ten weeks after harvest. These samples were analysed for residues and results are discussed in Section 2.3.

2.1.4 Drift of Insecticide Study 18 (Ref. Main Report, Annex A.1 and A.3)

The data given in the main report on g.l.c. analysis of insecticide drift, assessed as a proportion of the estimated in-field deposition of wool collectors, excluded that on the trial carried out at Rahad on whitefly control. For sake of completeness these data are given here in Tables 2.6 and 2.7 and were obtained from the standard application treatment. Table 2.2 should be referred to for the amounts of insecticide collected.

Recovery of insecticide drifting downwind was of the same order as the other studies, and showed a similar pattern of drift whereby the great proportion of chemical fall-out occurred within 100 m of the field-edge. Deposition of endosulphan was rather higher than the norm at 250 and 500 m but not very much so. These data further substantiate the conclusions given in the main report.

TABLE 2.6 SUMMARY OF SPRAY DROPLET SIZE AND COVER ON DOWNWIND SAMPLES (STUDY 18,WHITEFLY CONTROL)

2.2 SOIL RESIDUES

2.2.1 General

Results of soil sample analysis for Temik (aldicarb) residues have been presented in the main report (Ref. Section 3.2.9). Three other fields were sampled twice during the season, and soils were analysed for residues of the range of insecticides which had been applied during the season onto those fields. Results are presented in Table 2.8. Data on application is given in Tables 2.10 and 2.11.

2.2.2 Methodology

Soil samples were taken as two replicates from each field at each sampling date. Sample pits were randomly sited along a line walked at right angles to the field edge and aircraft flight path, inward from the downwind side and about 1/3rd along from the end. Four small pits were dug and bulked for each replicate, two were in the cotton row on the ridge and two were inter-row in the furrow, although by February the ridges had almost flattened. The eight pits extended about halfway across the field. Samples were taken at three depths, 0-3: 3-10: 10-20 cms, and care was taken to avoid contamination between depths. The samples were placed in cotton bags and transported to the laboratory where, after mixing and subsampling of 600-700 grams, the samples were wrapped in aluminium foil, placed in polythene bags and deep frozen. Transportation to UK for analysis was in insulated cool boxes. Details on the gas liquid chromatography procedures are given in Appendix B together with the original analytical data. Control samples were taken from untreated bush, untreated rough grazing and untreated fallow. Results from analyses are given in Table 2.8.

2.2.3 Results and Pollution Hazard

Few of the insecticides left residues that were detectable by routine Gas Chromatography methods and two of those showing readily measurable residues, aldicarb and thiometon, were at low enough concentrations (ppb) not to pose an unacceptable hazard to

the soil micro-organisms. Both are quite highly soluble in water and thus mobile and degradeable (Ref. Main Report, Section 3.2.9). The level of endosulfan residues are high enough to give cause for some concern however.

High levels of endosulfan were recorded from Block 9 Seed Farm for samples taken on November 21st between one and two hours after application of endosulphan plus thiometon (Table 2.10). The level of 2.39 ppm thus reflects accurately the deposition on the soil surface immediately after this sixth application of endosulfan. With seven applications over the season the total surface deposit would be greater than 16.8 ppm, since a greater proportion of early spray would penetrate to the soil surface. Levels in the surface layer had declined to 0.295 ppm after 80 days. The residue levels at lower depths for the November 21st sample are cumulative of five sprays applied between September 30th and November 12th, from which downward movement of the insecticide will have occurred following irrigation, and show similar decline by February. Similar considerations apply to thiometon (Table 2.9).

This fall in residue levels between mid-season and late season sampling dates was found with all insecticides having detectable residues except in Block 37, where no detectable residues were found in the mid-season samples. It is clear from these results that insecticide deposited on the soil during spraying is broken down rapidly over the season and immediately afterward, to very low levels which in general are no threat to the environment in the long-term. A possible exception to this is endosulphan as evidenced by the levels of 240 ppb in rough grazing control and 30 ppb in the 'clean' control sampled from uncultivated bush several kilometers from the nearest sprayed area and presumably due to drift accumulations. There is also an indication that endosulfan may accumulate in the upper 0-3 cm layer in cultivated soils, which is in agreement with its low solubility in water ($\triangleq$ 0.33 mg/l for both isomers at 22°C). Stability to sunlight and heat under Sudan conditions is unknown but is likely to be good to moderate. It would be subject to loss by evaporisation due to relatively high volatility. Little data is available on the persistance of endosulfan in tropical soils but the concern stems from considerations such as its half-life. Five to 45 days has been recorded in Indian soil; from application of 1.5 kg a.i./haa 63% reduction from a 0.55 ppm residual concentration in two months has been recorded (Ref.5).

Information on effects on soil organisms is also sparse from tropical soils. Microbial growth (bacteria and fungi) is inhibited at higher concentrations (400 ppm) but not at low ones (240 ppm) in culture, and at low concentrations degradation by bacteria and fungi is accelerated (Ref. 6). Other workers have demonstrated that in pure culture many organisms can degrade the isomers and breakdown products of endosulfan. Micro-organisms from the rhizosphere of rice fields showed insignificant changes in population after 20 days exposure. (Conc. unknown). Nitrogen fixation by *Rhizobium* from *Phaseolus aureus* and breakdown of organic matter were unaffected.

The physical and biological results from the intensive repetitive spraying of endosulfan plus potentiating compounds practised by the Sudan cotton producing boards will depend on soil type and environmental factors. Under a less intensive system breakdown should be rapid, taking account of the relative solubility of endosulfan as compared with other organo-chlorines, its volatility and the temperature and light intensity of the Gezira.

It is concluded that no significant hazard exists to soils micro-organisms or processes from aldicarb, thiometon or the other insecticides as currently used on the Gezira excepting possibly from endosulfan. More work on effects on non-target soil organisms in these soils is necessary before drawing conclusions on this compound.

2.3 INSECTICIDE RESIDUE IN FOODSTUFFS

2.3.1 General

The possibility that insecticide drift when spraying cotton will contaminate neighbouring sorghum crops or vegetables grown near to villages, which is an increasingly important farming activity, was assessed. Unfortunately only a total of 10 samples could be checked since analysis had to be made in the United Kingdom.

2.3.2 Methodology

Duplicate sets of samples were taken in the same Blocks as were sampled for soil residue analysis, and near the villages where blood cholinesterase levels were being monitored.

Mid-season sorghum samples were taken by cutting several heads just prior to harvest from edges of fields. The grains were cut from the main stem with minimal disturbance, bulked and packed in aluminium foil placed in plastic bags and frozen. As soon as possible the frozen heads were transported to UK in insulated cool boxes. In February, 10 weeks after harvest, grain samples were taken from farm stores in villages near to the sampled blocks and processed in the same way.

Vegetables were sampled from fields in the same areas where possible and frozen as for sorghum.

2.3.3 Results and Hazard Assessment

Results are summarised in Tables 2.12 and 2.13 with full data in Appendix C. The schedule of sprays applied are given in Table 2.10 for Blocks 37, 7 and 9, and in Table 2.14 for Blocks 5, 20 and 95.

These data indicate the potential for contamination of the sorghum samples quite accurately, but less so for vegetables. The Gezira recommended rates of application are shown in Table 2.11.

- Sorghum

  In one sample of grain from sorghum heads taken in the middle of the spray season relatively high residues of four chemicals were found. In the stored grain, however, all residues were very low or below the limit of detection. Of these four chemicals the levels of endosulphan, triazophos and chlorpyrifos were of the order indicated by theoretical levels estimated in Section 2.1.3. From Table 2.14 it will be seen that six sprays of endosulphan had been made during the previous months on Block 5 and one of these plus chlorpyrifos was given the day before sampling, while triazophos had been sprayed two weeks prior. This indicates a reasonable relationship between residues and field application, and with estimated contaminations (Table 2.5). However, residues of the fourth chemical, amitraz, cannot be related. It was not sprayed at all in Block 5 according to records and the high residue level is perplexing.

  The levels of amitraz found in stored grain at 0.05, 0.19 and 0.17 ppm are well below the Maximum Residue Limit set by CODEX at 0.5 mg/kg amitraz plus metabolites. Residues in grain after milling and cooking would be further reduced. The Acceptable Daily Intake has been set (1984 JMPR) at 0.003 mg/kg/day which provides a maximum permissable intake of 0.18 mg/day for a 60 kg person. Workers in Sudan may consume 600 grams of grain per day, which at the residue levels found would contain 0.084 mg, under half the permissable intake, without taking account of further breakdown in milling and cooking.

** Frame spray to edges of numbers only.*

Table 2.15 shows similar estimations for the other detected insecticides. Tolerance levels for endosulphan residues in grain sorghum appear not to be established but for wheat and barley are 0.1 mg/kg and for maize is 0.2 mg/kg. From this it appears that pesticide residues in sorghum grain resulting from airspray to cotton pose no hazard to man or livestock.

- Vegetables

The analytical results for vegetables show most insecticide residues to be below the limits of detection. Endosulphan residues detected in peppers and okra sampled in mid season are well below the tolerance levels established by FAO or other countries for similar vegetables (tomato, cucumber, aubergines) at 0.5 to 2.0 mg/kg. Again these appear to cause no hazard to consumers.

TABLE 2.15 ESTIMATED INTAKE OF PESTICIDE RESIDUES IN SORGHUM GRAIN BY A TYPICAL SUDANESE WORKER

	Detected Residue PPM	No. Samples	Estimated Intake (as total[1]) mg/day	Estimated Intake (by bodyweight[2]) mg/kg
Amitraz	0.14	3	0.084	0.0014
Endosulphan	0.06	3	0.036	0.0006
Dimethoate	0.08	3	0.048	0.0008
Triazophos	0.02	2	0.016	0.0003
Cypermethrin	0.07	1	0.042	0.0007
Fenvalerate	0.04	1	0.024	0.0004

Note: [1] *Assumed average daily consumption as 600 g sorghum as dough (kisra; asida; etc).*
[2] *Assumed weight of worker 60 kg.*

- Grain eating birds

A possible hazard to migrant and indigenous grain-eating birds exists, including species classed as pests. The degree of hazard is difficult to assess as data on No Effect Levels (NEL) for the comounds under consideration could not be obtained, and in fact does not exist in sufficient detail to forecast toxicity for the range of species which may be involved. If the data available for quail and pheasant are considered there appears to be a low level of hazard. Assuming quail weigh 250 g and eat 50 g sorghum grain per day, and taking the highest residue figures, they would consume about 0.17 mg triazophos or 0.015 mg quinalphos. The LD50 values are 1.1 mg and 7.5 mg. While there is no hazard with quinalphos there seems to be a slight possibility that triazophos might accumulate to toxic levels where the quail feeds repetitively for a week or more. This depends on the rate of breakdown in the bird. Where a 1 kg pheasant is assumed to eat 200 g grain per day it would consume 0.024 mg dimethoate or 0.7 mg endosulphan. The LD50 values here are 15 mg and 620 mg, far in excess of the amount consumed, with both chemicals being rapidly metabolised. In general the degree of hazard to bird life seems very low but the possibility of adverse effects on reproduction should be borne in mind.

LD50 data (Ref. Pesticide Manual)

Amitraz	(Quail)	1800 mg/kg diet
Dimethoate	(Pheasant)	15 mg/kg
Endosulphan	(Pheasant)	620-1000 mg/kg
Quinalphos	(Quail)	150 mg/kg diet
Triazophos	(Quail)	42-27.1 mg/kg

2.4 INSECTICIDE RESIDUE IN WATER

2.4.1 General

The principle source of water for human consumption on the Gezira is now from boreholes, reported to average 30-40 m deep, but workers will not hesitate to drink from canals when working in the fields. On other production areas water from canals is rather more frequently drunk. In order to assess the level of contamination likely to be encountered water from a canal passing a small village, and from a household standpipe in the village was sampled for analysis.

At Geiger in the south White Nile production area the pesticide store is sited badly with high probability of contamination of a minor canal passing 10 m from old leaking drums, from which water for domestic purposes is drawn 20 m and 200 m downstream. This was considered the most seriously hazardous storage site encountered, and a water sample was drawn from the canal to check contamination.

2.4.2 Methodology

Water samples were drawn directly into new liquor bottles thoroughly washed out with iso-propyl alcohol. The bottles were kept in an efficient domestic refrigerator until they could be transported to UK for analysis in insulated cool boxes, except for sample W9, from White Nile which was frozen until four days before despatch. One sample, W4, was broken in transit. Unfortunately it was not possible to arrange for the samples to be extracted by collaborators in Sudan since the required solvents could not be obtained in time, and as a result the numbers of samples and hence sites had to be severely reduced.

2.4.3 Results and Hazard Assessment

Results of analyses are summarised in Table 2.16, with full data in Appendix D. The canal sampled, Abu Galil, was in Block 20. Table 2.14 details the chemicals applied over the season.

No aldicarb was used in Messallamia Group area in 1985, and none has ever been used in the White Nile cotton area. A routine analysis was however carried out with no residues being detected. The question of aldicarb residues in village water sources is further discussed in Main Report Annex B1, giving results of the survey carried out by the Consortium for International Crop Protection in which they conclude that the chance of aldicarb reaching village water sources near to fields in which aldicarb has been used is remote.

Over the three month period sampled, mid to late season, no detectable residues were found in tap water, except endosulphan at 0.01 ppb in one sample. There seems to be little chance of insecticide residues leaching into the groundwater to cause environmental contamination nor any hazard from use of borehole water by man or livestock.

The highest levels of residues reported from canal water would also not be hazardous to man. Where a 60 kg man is assumed to drink 5 l water per day his intake of insecticide would fall well below the Acceptable Daily Intake levels set for drinking water as follows:

	A.D.I.	For 60 kg man	Actual Intake
Endosulphan	0.008 mg/kg	0.48 mg/man	0.049 mg
Chlorpyrifos	0.01 mg/kg	0.60 mg/man	0.015 mg
Dimethoate	0.02 mg/kg	1.20 mg/man	0.001 mg
Thiometon	0.003 mg/kg	0.18 mg/man	0.005 mg
Profenofos	None Established	-	0.006 mg

2.5 OVERALL HAZARD ASSESSMENT - WAD SHANNAN VILLAGE, BLOCK 7 SOUTH GROUP

In their proposal the Consultants planned to select two Blocks, in the north and south areas of the Gezira, in which an in-depth hazard assessment would be carried out. Problems in coordination of the airspray monitoring studies with other project activities and with commercial application problems made this impossible in the north, but it was satisfactorily undertaken in South Group.

The village of Wad Shannan was selected since it is small and situated halfway along a cotton number so that the spray aircraft overflew the village each pass. While spray application was cut off each time hazard from drift and direct contamination was inveitably higher. The Numbers adjacent to cotton on the south, downwind side were fallow, which allowed easy drift assessment. Finally there was a dispensary near by with an exceptionally able and well known medical assistant who organised a village blood cholinesterase monitoring programme.

Overall hazard assessment is based on the following studies:

(i) Villagers Blood Cholinesterase Monitoring - 153 tests

(ii) Downwind Insecticide Drift - two studies

(ii) Soil Sample Residue Analysis - aldicarb

(iv) Soil Sample Residue Analysis - general

(v) Vegetable Residue Analysis - general

(vi) Sorghum Grain Residue Analysis - general

Sorghum head and other vegetable samples were obtained in neighbouring blocks, but unfortunately no water samples were taken in the area, due to limitations on numbers of analyses possible. Results on sections (ii) to (vi) have been discussed in detail in the main report and other parts of this volume.

Table 2.17 summarises the data on blood tests. Both the Indirect Contact group, which comprised farmers and field workers, and the No Contact group showed sharp declines in the percentage of normal (100 per cent) test results as compared to the average for all tests in the Southern Gezira area for the same groups. This was no doubt due to the location of the village. However since this drop was only to 87.5 per cent and 75 per cent of normal levels there is no cause for concern regarding the general health of the villagers and farmers of Wad Shannan . None of the villagers returned levels below 75 per cent of normal. These results substantiate the conclusions drawn in Sections 2.2, 2.3 and 2.4 of this volume, and in Chapter 8 of the main report, that air-spraying as practised at present in the Sudan Gezira poses a low level of hazard to villagers, the general public and the general environment, with those reservations already stated regarding the repetition use of endosulphan.

TABLE 2.17 SUMMARY BLOOD CHOLINESTERASE TESTS - WAD SHANNAN

Numbers of Persons Tested

CHAPTER 3

THE APPLICATION OF INTEGRATED PEST MANAGEMENT (IPM) TECHNIQUES TO SUDAN COTTON

3.1 BACKGROUND

The SGB Crop Protection Department have proposed that an integrated pest management strategy should be already implemented as the basis for control of cotton pests by 1990. In fact some components of such a system have been practised for many years, for example the close season for cotton on the Gezira and introduction of hairy Acala varieties having jassid resistance (but also being susceptible to whitefly). However application of chemicals remains the major method of control at present. Experience over the last 10 years shows that, unless there is a change in the fundamental approach to pest control, cotton production will cease to be economic in the Sudan. This has been emphasised by many visiting experts and an FAO/UNEP project to set up a basis for introduction has been operating for about six years in collaboration with ARC, Wad Medani. Field scale implementation of IPM will require some fundamental changes by SGB field staff, not only in practice but in the attitude and approach to pest control. It is therefore useful to define the IPM concept and assess what changes its introduction may impose on SGB and other Corporations.

3.2 THE CONCEPT

The concept of integrated pest control envisages the use of all possible control methods to reduce insect pest damage to a level that is economically acceptable. This is opposed to reliance on schedules of insecticide sprays as the principle way of control. Integrated control includes the use of resistant or tolerant varieties, the manipulation of sowing dates, the adoption of agronomic practices that avoid excessively verdant growth, biological control - both natural and artificial, (the use of viruses, fungi and bacteria), and that most basic practise of cotton sanitation, the close season. The concept accepts that the use of insecticides will be an integral part of any control systems, provided that their use is as and when pest populations rise to levels requiring application despite other control measures. Thus the timing of insecticide application is critical and dependant on a knowledge of that population of a particular pest which will result in yield loss or quality reduction, if not controlled. As noted in Chapter 7 of the main report this population level may be termed the economic threshold if sufficiently detailed knowledge is available. Alternatively, and more practically, it may be termed the 'action level' or 'action threshold' (Sterling and Lincoln 1977, Main Report, Ref. 32) because by definition of 'economic threshold' a great number of variables have to be taken into account and the threshold will vary from season to season. The complexity may be illustrated by noting some of the variables that have been taken into account by Sterling and Lincoln (1977). These apply to most pest control situations, but here *Heliothis armigera* is specifically considered. The variables include:

1. Variation of climate and its effect on the development of the cotton plant and on *Heliothis* and other pest populations

2. Cotton variety

3. Economic factors that may fluctuate annually:
   - sale price of cotton
   - cost of application of insecticides
   - cost of alternative control measures
   - other production costs

4. Cropping practises

5. Consideration of measures to delay onset of insecticide resistance in the *Heliothis* population

6. Influence of insecticide spraying on potential biological control organisms and on potential secondary pest development

7. Variation in potential yield associated with variable soil fertility

8. Fluctuation of *Heliothis* adult populations and their movement between host crops. (This may be monitored by use of pheromone traps)

9. Spatial distribution of larvae on the plant related to growth stage, i.e. which part of plant is chosen for sampling, and to non-random oviposition (clumping or aggregation)

10. The relationship between boll-loss caused by *Heliothis* and other factors such as boll-rot, *Fusarium*, nematodes and other insect pests

11. The efficiency of the sampling system. If this is inadequate the whole concept collapses since data on populations is unreliable

Some of the factors are already taken into consideration by SGB (Main Report, Appendix I, Ref. 6).

The scope for application of IPM has been discussed by the Consultants in an earlier project in 1983 (Main Report, Appendix I, Ref. 7) with regard to whitefly, as well as by a number of other authorities, and warrant no further discussion here.

3.3 IMPLEMENTATION BY SGB

3.3.1 Scouting

Timing of applications is critical to IPM. The first step has been taken already in that 'Marginal, Partial or Selective spraying is recommended' and this has lead to reduction of spraying, particularly early and late in the season as compared to blanket spraying of whole Numbers when the spray threshold is exceeded. The expression of the potential of beneficial insects to aid pest control can only be realised by delaying early season applications as long as possible. Delaying early application can only be instituted where (i) a good knowledge of the pest populations and (ii) the early season spray action thresholds is obtained. The second of these is the responsibility of research. The first will require general upgrading of the scouting system as has been discussed in Chapter 7 of the main report. An efficient, scheme-wide, uniform scouting system is critical to introduction of IPM. It will involve SGB in increased expenditure on recruiting permanent scouts, training, transportation and possibly communications.

3.3.2 Agronomic Practises

A number of these have great influence on development of whitefly, notably application of nitrogen, length of the planting season, thinning and uniformity of irrigation. The most critical is the cut-off date for irrigation. These have all been discussed in the main report and thus need no elaboration here, but their acceptance, notably of earlier cessation of irrigation, will require a major extension exercise to educate farmers, and even of management staff at all levels.

3.3.3 Resistant Varieties

Varieties resistant to whitefly are being bred in Sudan and the first, Sudac K, has been released. It has not been popular with farmers (Dr H. Khalifa, Pers. Com.) because of the lower yield when compared to Acala varieties. This implies that prices in relation to variety and quality, as expressed by reduced stickiness, will have to be reviewed. Changes in pricing policy by the Cotton Production Corporation will be needed. Again a major farmer education programme would seem necessary, which will need to include appropriate changes in cultural practices.

3.3.4 Biological Control - Beneficial Insects

If the potential of parasites and predators are to be realised the policy on insecticide selection may have to be altered, as well as delaying early season spraying to the economically justifiable maximum. The present policy requires that the same mixture may not be applied more than once to any Block during one season. This is designed to postpone development of resistance in the insect population.

Recent experience is that certain insecticides and mixtures are particularly potent against beneficials. The Decis/dimethoate ULV mixture is suspect while other insecticides need to be screened for potency. If one or more chemicals or modes of application cause little disruption of beneficials then these should be preferred and their use repetitively will need consideration. Examples are:

- selective chemicals e.g. pirimicarb for aphids
- short residual effect with stomach action
- soil or seed treatment with systemics
- strip or spot spraying

Full introduction of each of these would require changes, or more rigorous implementation, of SGB policies.

Assessment of potential for biological control can only be properly investigated by allocation of a substantial block of cotton to be left unsprayed and observed over several seasons. (Ref. Main Report, Section 8.3.5).

CHAPTER 4

RESEARCH REQUIRED

It is not within the Terms of Reference of this project to comment on research needs but at informal discussions with the Acting Director of the Agricultural Research Council at Wad Medani it was suggested comments could be useful. Subsequently the 1986 draft programme for cotton research was passed to the Consultants. The following suggestions are made on the basis of information and experience acquired over the 1985-86 season by the Consultants.

4.1 ACTION THRESHOLDS

The need for the present thresholds to be reviewed and researched has been discussed fully in the Main Report. The outline of a major research project, 'Establishment of the Economic Thresholds for the Major Cotton Pests', is included in the ARC programme as small scale replicated field trials. If the selected levels of infestation can be maintained in the plots this will provide valuable information. It is suggested that large scale field trials should also be undertaken in which treatment with insecticides would vary according to pest population levels. Two series of trials could be carried out, Early and Late season. In the early season (September to early November) interferance by jassid with *Heliothis* could be diminished by use of a selective systemic, while in the late season trial similar use of pirimicarb would reduce interferance by aphid on the whitefly damage. Standard Treatments would follow or precede the trial period.

4.2 SCOUTING SYSTEMS

The system used in Sudan has been discussed in detail in the main report and recommendations have been made to improve the system and results obtained. Anticipating the introduction of IPM systems and the greater need for precise pest counts it is suggested that sequential scouting using charts based on in-depth knowledge of population dynamics and pest-related damage. Development of these plans would take several years in absence of data. There should however be much valuable data in SGB crop protection department dating over many years and research personnel could process these data to prepare initial sampling plans.

It is appropriate here to again emphasise the importance of uniform scouting procedures with specially trained teams being used for any pesticide performance assessments as well as for formal trials.

4.3 INSECTICIDE SCREENING IN THE LABORATORY

The introduction of routine insecticide screening is recommended as being critical to assessment of insecticides within an IPM programme. Bioassay of insecticides helps to determine:

- the most effective compounds
- possible onset of insecticide resistance and cross resistance
- the quality of carryover stocks of insecticide
- which chemicals have least effect on beneficial insects

The immediate result of this screening would be to cut down the number of new chemicals or formulations going through to large scale field trials, thereby releasing staff for

more important work and cutting costs. A further important aspect is that screening continues throughout the year, thereby permitting more data to be accumulated. One advantage of using laboratory reared insects is that a standard population is used for all basic assessment and that conditions can be carefully controlled.

4.4 BENEFICIAL INSECTS

Three coleopterous predators were identified in the field studies as being of potential value for biological control. These are *Scymnus marginalis, Coccinella rufresceus* and *Cydonia vicina,* and they represented 61 per cent of the predators collected in the sweep net sampling. It is recommended that investigation be undertaken into their efficacy as predators and if this proves satisfactory the possibility of artificial rearing and mass release should be examined.

More general recommendations for research are given in Section 8.3.5 of the main report.

4.5 GROUND APPLICATION

Certain areas of cotton can never be sprayed by air, e.g. adjacent to power lines and telephone cables. Air spray contractors are supposed to spray these from the ground but this is seldom carried out. Control of whitefly by airspraying is clearly often poor and sometimes totally ineffective. The use of ground application methods should be re-examined. This has become a practical proposition now that tractors using very low pressure tyres have been developed together with spray equipment that applies insecticides spraying upwards from near the ground to give good under surface cover to the leaves. It is recommended that these possibilities be investigated for better whitefly control.

4.6 RATES OF APPLICATIONS AGAINST WHITEFLY

In view of the difficulties of controlling whitefly adults with residual insecticides and the tolerance of whitefly nymphs to all insecticides, the possibility of controlling mobile adults seems worth examination, since some newer chemicals have a considerable "knock-down" effect. These can be applied as ULV oil formulations drift sprayed across 200-300 m swaths, permitting low overall rates of application. Daily spraying at these low rates aimed at killing the adults as they emerge should lead to rapid population reductions by eliminating egg laying. Daily spraying using 200 or 300 m swath widths should more or less equate with weekly spraying at 25 m swaths. It is suggested this possibility be investigated to ascertain how long daily spraying would have to continue to reduce populations to an acceptable level, and how long it takes before spraying has to start again. It is emphasised that rates of application could be reduced to a few per cent of present levels and that similar methods have been successfully tried in other crops.

Graham A. Taylor, B.Sc.,
Study Analyst,
Department of Analytical Chemistry.

HRC Project Number: HTS/2.

Date of commission: This work was commissioned by Mr. C. R. Whetnall of Hunting Technical Services Ltd on 12th November 1985.

Samples: Samples were received between 22nd October 1985 and 17th February 1986 in a good condition and stored at -20°C prior to analysis.

Study: Residue analysis.

Method: The samples were analysed by soxhlet extraction for 2 hours with dichloromethane. Extracts were concentrated using Kuderna-Danish evaporator containing 1 ml of toluene as keeper. Extracts were made up to volume (2.0 ml) with 2,2,4-trimethylpentane and retained for quantitation by gas-liquid chromatography using conditions detailed in Appendix 1.

Results: The results obtained, uncorrected for control or procedural recovery values, are shown in Tables 1-19. Procedural recovery values, corrected for appropriate control residues, are shown in Tables 20-31.

Results are reported as micrograms insecticide found per metre length of acrylic wool (µg/m).

Endosulphan is reported as the total of alpha and beta isomers.

Procedural recoveries were carried out using commerically available acrylic wool, previously cleaned by soxhlet extraction with both acetone and dichloromethane. On each occasion a 3.0 m length of acrylic wool was spiked with a 1.0 ml solution of appropriate insecticide mixture. The solvent was allowed to evaporate and the sample extracted and analysed concurrently with the field treated samples.

As control samples supplied from Sudan were contaminated by the compounds sprayed, results from HRC control samples are also reported.

Typical analytical chromatograms are shown in Figures 1-12.

APPENDIX 1/1

Gas chromatographic conditions used for the determination of Alphamethrin

Instrument: Hewlett Packard 5710A gas chromatograph fitted with a ^{63}Ni electron capture detector and HP 7671A automatic sampler.

Column: 2 m x 2 mm i.d. glass packed with 1.5% SP 2250 + 1.95% SP 2401 on Supelcon (100-120 mesh).

Temperatures:

Injector	300°C
Column	270°C
Detector	300°C

Gases:

Carrier

Argon/Methane 35 ml/minute.

Injection volume: 5 µl.

Under these conditions alphamethrin had an approximate retention time of 4.5 minutes.

APPENDIX 1/2

Gas chromatographic conditions used for the determination of Amitraz

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a nitrogen phosphorous thermionic specific detector and HP 7671A automatic sampler.
Column:	1.8 m x 2 mm i.d. glass packed with 5% OV 210 on Diatomite CLQ (100-120 mesh).
Temperatures:	
Injector	250°C
Column	200°C
Detector	300°C
Gases:	
Carrier	
Helium	35 ml/minute
Flame	
Hydrogen	3 ml/minute
Air	60 ml/minute.
Injection volume:	5 µl.

Under these conditions amitraz had an approximate retention time of 4 minutes.

APPENDIX 1/3

Gas chromatographic conditions used for the determination of Chlorpyrifos

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a flame photometric detector, in the phosphorus mode, and HP 7671A automatic sampler.
Column:	1 m x 4 mm i.d. glass packed with 2½% Apiezon L on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	250°C
Column	205°C
Detector	250°C
Gases:	
Carrier	
Nitrogen	40 ml/minute
Flame	
Hydrogen	200 ml/minute
Oxygen	15 ml/minute
Air	50 ml/minute.
Injection volume:	10 µl.

Under these conditions chlorpyrifos had an approximate retention time of 1.8 minutes.

APPENDIX 1/4

Gas chromatographic conditions used for the determination of Cypermethrin

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a ^{63}Ni electron capture detector and HP 7671A automatic sampler.
Column:	2 m x 2 mm i.d. glass packed with 1.5% SP 2250 + 1.95% SP 2401 on Supelcon (100-120 mesh).
Temperatures:	
Injector	300°C
Column	270°C
Detector	300°C
Gases:	
Carrier	
Argon/Methane	35 ml/minute.
Injection volume:	5 µl.

Under these conditions cypermethrin had an approximate retention time of 4.4 minutes.

APPENDIX 1/5

Gas chromatographic conditions used for the determination of Decamethrin

Instrument: Hewlett Packard 5890 gas chromatograph fitted with a ^{63}Ni electron capture detector and a 7672A automatic sampler.

Column: 1.5 m x 3 mm i.d. glass packed with 1% SE 30 on Diatomite CLQ (80-100 mesh).

Temperatures:

Injector	300°C
Column	260°C
Detector	300°C

Gases:

Carrier

Nitrogen 60 ml/minute.

Injection volume: 3 µl.

Under these conditions decamethrin had an approximate retention time of 2.6 minutes.

APPENDIX 1/6

Gas chromatographic conditions used for the determination of Dicrotophos

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a nitrogen phosphorous thermionic specific detector and HP 7671A automatic sampler.
Column:	1.4 m x 2 mm i.d. glass packed with 5% OV 210 on Diatomite CLQ (100-120 mesh).
Temperatures:	
Injector	250°C
Column	210°C
Detector	300°C
Gases:	
Carrier	
Helium	35 ml/minute
Flame	
Hydrogen	3 ml/minute
Air	60 ml/minute
Injection volume:	5 µl.

Under these conditions dicrotophos had an approximate retention time of 1.5 minutes.

APPENDIX 1/7

Gas chromatographic conditions used for the determination of Dimethoate

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a flame photometric detector, in the phosphorous mode, and HP 7671A automatic sampler.
Column:	1 m x 4 mm i.d. glass packed with 2½% Apiezon L and Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	250°C
Column	180°C
Detector	250°C
Gases:	
Carrier	
Nitrogen	40 ml/minute.
Flame	
Hydrogen	200 ml/minute
Oxygen	15 ml/minute
Air	50 ml/minute.
Injection volume:	10 µl.

Under these conditions dimethoate had an approximate retention time of 1.7 minutes.

APPENDIX 1/8

Gas chromatographic conditions used for the determination of Endosulphan

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a ^{63}Ni electron capture detector and HP 7671A automatic sampler.
Column:	1.8 x 2 mm i.d. glass packed with 3% OV 101 on Chromosorb W-AW-DMCS (100-120 mesh).
Temperatures:	
Injector	250°C
Column	230°C
Detector	300°C
Gases:	
Carrier	
Argon/methane	30 ml/minute
INjection volume:	5 µl.

Under these conditions α endosulphan had an approximate retention time of 2.6 minutes, and β endosulphan had an approximate retention time of 3.3 minutes.

APPENDIX 1/9

Gas chromatographic conditions used for the determination of Fenvalerate

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a ^{63}Ni electron capture detector and HP 7671A automatic sampler.
Column:	0.5 m x 4 mm i.d. glass packed with 3% SF 96 + 3% Apiezon M on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	300°C
Column	270°C
Detector	300°C
Gases:	
Carrier	
Argon/Methane	30 ml/minute
Injection volume:	5 µl.

Under these conditions fenvalerate had an approximate retention time of 2.2 minutes.

APPENDIX 1/10

Gas chromatographic conditions used for the determination of Quinalphos

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a flame photometric detector, in the phosphrous mode, and HP 7671A automatic sampler.
Column:	1 m x 4 mm i.d. glass packed with 2½% Apiezon L on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	250°C
Column	210°C
Detector	250°C
Gases:	
Carrier	
Nitrogen	40 ml/minute
Flame	
Hydrogen	200 ml/minute
Oxygen	15 ml/minute
Air	50 ml/minute
Injection volume:	10 µl.

Under these conditions quinalphos had an approximate retention time of 2.1 minutes.

APPENDIX 1/11

Gas chromatographic conditions used for the determination of Thiometon

Instrument: Hewlett Packard 5710A gas chromatograph fitted with a flame photometric detector, in the phosphorus mode, and HP 7671A automatic sampler.

Column: 1 m x 4 mm i.d. glass packed with 2½% Apiezon L on Diatomite CLQ (80-100 mesh).

Temperatures:

Injector	250°C
Column	205°C
Detector	250°C

Gases:

Carrier	
Nitrogen	30 ml/minute
Flame	
Hydrogen	200 ml/minute
Oxygen	15 ml/minute
Air	50 ml/minute

Injection volume: 10 µl.

Under these conditions thiometon had an approximate retention time of 1.4 minutes.

APPENDIX 1/12

Gas chromatographic conditions used for the determination of Triazophos

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a flame photometric detector, in the phosphorus mode, and HP 7671A automatic sampler.
Column:	1 m x 4 mm i.d. glass packed with 2½% Apiezon L on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	250°C
Column	220°C
Detector	250°C
Gases:	
Carrier	
Nitrogen	40 ml/minute
Flame	
Hydrogen	200 ml/minute
Oxygen	15 ml/minute
Air	50 ml/minute
Injection volume:	10 µl

Under these conditions triazophos had an approximate retention time of 2.7 minutes.

HRC

HRC Project number: HTS 4.

Date of commission: This work was commissioned by Mr. C.R. Whetnall of Hunting Technical Services Ltd on 12th November 1985.

Samples: Samples were received between December 1985 and March 1986 in a good condition and stored at -20°C prior to analysis.

Study: Residue analysis.

Method:

1. Aldicarb

The samples were analysed by shaking with 90% v/v acetone in water for 3 hours. An aliquot was evaporated to the aqueous layer, toluene and peracetic acid added and the mixture agitated for 30 minutes to oxidise the aldicarb to aldicarb sulphone. The mixture was neutralised with 10% aqueous sodium hydrogen carbonate solution, washed with hexane and the aqueous phase extracted with chloroform. The chloroform extract was dried using anhydrous sodium sulphate, added to a Florisil clean-up column and eluted with 5% v/v acetone in diethyl ether and 25% v/v acetone in diethyl ether. The latter fraction was collected, evaporated to dryness and taken up in acetone for analysis by GLC using the conditions detailed in Appendix 1a.

2. Amitraz, endosulphan, organophosphorus compounds and pyrethroids

A bulk extract was prepared by moisturising samples with water and shaking with chloroform for 2 hours. An aliquot was then evaporated to dryness and the residue taken up in 1 ; 1 toluene ; 2,2,4-trimethylpentane for quantitation by GLC.

a) Amitraz was quantified using an OV-101 column and a nitrogen phosphrous thermionic specific detector, using conditions detailed in Appendix 1b.

b) Endosulphan was quantified using an OV-210 column and electron capture detector, using conditions detailed in Appendix 1c.

c) Organophosphorus compounds were quantified using an Apiezon L column and flame photometric detector, in the phosphorus mode, using conditions detailed in Appendix 1d.

d) Pyrethroids were quantified using an OV-101 column and electron capture detector, using conditions detailed in Appendix 1e.

Results:

The results obtained, uncorrected for control or procedural recovery values are shown in Tables 1-5. Endosulphan is reported as the total of α and β isomers. Procedural recovery values, corrected for appropriate control residues, are shown in Tables 6-17.

Typical analytical chromatograms are shown in Figures 1-5.

Samples 1 to 9 were for aldicarb residues in numbers treated in 1982, 1983, 1984 while under cotton. Each field sampled at three depths.

The HRL results are summarised in this report in Table 2.8 as means of replicates for the sampling dates A + B and C + D.

APPENDIX 1a

Gas chromatographic conditions used for the determination of Aldicarb as Aldicarb sulphone

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a nitrogen phosphorous thermionic specific detector and HP 7671A automatic sampler.
Column:	2 m x 4 mm i.d. glass packed with 5% DC 200 + 2% Carbowax on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	250°C
Column	190°C
Detector	300°C
Gases:	
Carrier	
Helium	30 ml/minute
Flame	
Hydrogen	3 ml/minute
Air	80 ml/minute.
Injection volume:	10 µl.

Under these conditions Aldicarb sulphone had an approximate retention time of 3.9 minutes.

APPENDIX 1b

Gas chromatographic conditions used for the determination of Amitraz in soil

Instrument:	Hewlett Packard 5890 gas chromatograph fitted with a nitrogen phosphorus thermionic specific detector and HP 7672A automatic sampler.
Column:	1.8 m x 2 mm i.d. glass packed with 5% OV-101 on Diatomite CLQ (100-120 mesh).
Temperatures:	
Injector	250°C
Column	210°C
Detector	300°C
Gases:	
Carrier	
Nitrogen	35 ml/minute
Flame	
Hydrogen	5 ml/minute
Air	70 ml/minute.
Injection volume:	10 µl.

Under these conditions Amitraz had an approximate retention time of 7.2 minutes.

APPENDIX 1c

Gas chromatographic conditions used for the determination of Endosulphan in soil

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a ^{63}Ni electron capture detector and HP 7671A automatic sampler.
Column:	2 m x 4 mm i.d. glass packed with 5% OV-210 on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	300°C
Column	245°C
Detector	350°C
Gases:	
Carrier	
Argon/Methane	40 ml/minute.
Injection volume:	5 µl.

Under these conditions α-endosulphan had an approximate retention time of 4.3 minutes and β-endosulphan had an approximate retention time of 6.6 minutes

APPENDIX 1d

Gas chromatographic conditions used for the determination of organophosphorus compounds (chlorpyriphos, dimethoate, profenphos, quinalphos, thiometon, triazophos) in soil

Instrument:	Varian Vista 6000 fitted with a flame photometric detector in the phosphorus mode and an autosampler.
Column:	1 m x 2 mm i.d. glass packed with 2½% Apiezon L on Gas Chrom Q (100-120 mesh).
Temperatures:	
Injector	225°C
Column	130°C (1 min) $\xrightarrow{25°/min}$ 200°C $\xrightarrow{3°/min}$ 210°C $\xrightarrow{50°/min}$ 270°C (6 min)
Detector	250°C
Gases:	
Carrier	
Helium	30 ml/minute
Flame	
Hydrogen	140 ml/minute
Air	170 ml/minute.
Injection volume:	8 µl.

Under these conditions the organophosphorus compounds had the following approximate retention times:

Chlorpyriphos	7.7 minutes
Dimethoate	4.8 minutes
Profenphos	9.2 minutes
Quinalphos	8.5 minutes
Thiometon	4.7 minutes
Triazophos	4.1 minutes

APPENDIX 1e

Gas chromatographic conditions used for the determination of pyrethroids (cypermethrin, decamethrin and fenvalerate) in soil)

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a ^{63}Ni electron capture detector and HP 7671A automatic sampler.
Column:	1 m x 4 mm i.d. glass packed with 1% OV-101 on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	300°C
Column	215°C (2 mins) ——— 8°C/min ⟶ 240°C (4 min)
Detector	300°C
Gases:	
Carrier	
Argon/Methane	60 ml/minute.
Injection volume:	5 µl.

Under these conditions cypermethrin, decamethrin and fenvalerate had approximate retention times of 3.8 minutes, 5.3 minutes and 4.6 minutes respectively.

DEPARTMENT OF ANALYTICAL CHEMISTRY

CERTIFICATE OF ANALYSIS

The Determination of Concentrations of Insecticides

in Food

HTS 5

23rd May 1986

HRC

Ian A. Macdonald, L.R.S.C.,
Head of Pesticide and Environmental Analysis,
Department of Analytical Chemistry.

Nigel A. Gillis, B.Sc., G.R.S.C., A.R.C.S.,
Study Analyst,
Department of Analytical Chemistry.

G. A. Taylor

Graham A. Taylor, B.Sc.,
Study Analyst,
Department of Analytical Chemistry.

HRC Project number: HTS 5.

Date of commission: This work was commissioned by Mr. C. R. Whetnall of Hunting Technical Services Ltd on 12th November 1985.

Samples: Samples were received between December 1985 and March 1986 in a good condition and stored at -20°C prior to analysis.

Study: Residue analysis.

Method: 1. Aldicarb in Sorghum grains

The samples were analysed by soxhlet extraction with acetone for 2½ hours and the extract evaporated to dryness. The residue was taken up in hexane and partitioned with acetonitrile and the acetonitrile then evaporated to dryness. Water and peracetic acid were added to oxidise the aldicarb to aldicarb sulphone, the acidic solution neutralised with sodium hydrogen carbonate and the aqueous phase extracted with chloroform. The chloroform extract was dried using anhydrous sodium sulphate, added to a Florisil clean-up column and eluted with 5% v/v acetone in diethyl ether and 25% v/v acetone in diethyl ether. The latter fraction was collected, evaporated to dryness and taken up in acetone for analysis by GLC using the conditions detailed in Appendix 1a.

2. i). Amitraz, endosulphan, organophosphorus compounds and pyrethroids in Sorghum grains

The samples were analysed by soxhlet extraction with ethyl acetate for 3 hours and the extract evaporated to dryness. The residue was taken up in hexane, partitioned with acetonitrile and evaporated to dryness. The residue was then dissolved in 1 : 1 toluene : 2,2,4-trimethyl pentane for analysis by GLC.

ii) Amitraz, endosulphan, organophosphorus compounds and pyrethroids in bird peppers, okra, cucumber and aubergines

The samples were macerated with ethyl acetate, the filtered extract evaporated to dryness and residue taken up in hexane. The hexane was partitioned with acetonitrile, the acetonitrile evaporated to dryness and residue dissolved in 1 : 1 toluene : 2,2,4-trimethyl pentane for analysis by GLC.

a) Amitraz was quantified using an OV-101 column and a nitrogen phosphorus thermionic specific detector, using conditions detailed in Appendix 1b.

b) Endosulphan was quantified using an OV-210 column and an electron capture detector, using conditions detailed in Appendix 1c.

c) Organophosphorus compounds were quantified using an Apiezon L column and flame photometric detector in the phosphorus mode, using conditions detailed in Appendix 1d.

d) Pyrethroids were quantified using an OV-101 column and electron capture detector, using conditions detailed in Appendix 1c.

Results:

The results obtained, uncorrected for control or procedural recovery values are shown in Tables 1-5. Endosulphan is reported as the total of α and β isomers. Procedural recovery values, corrected for appropriate control residues are shown in Tables 6-19.

Typical analytical chromatograms are shown in Figures 1-5.

HRC

APPENDIX 1a

Gas chromatographic conditions used for the determination of Aldicarb as Aldicarb sulphone

Instrument: Hewlett Packard 5710A gas chromatograph fitted with a nitrogen phosphorous thermionic specific detector and HP 7671A automatic sampler.

Column: 2 m x 4 mm i.d. glass packed with 5% DC 200 + 2% Carbowax on DCLQ (80-100 mesh).

Temperatures:

Injector	250°C
Column	190°C
Detector	300°C

Gases:

Carrier	
Helium	30 ml/minute
Flame	
Hydrogen	3 ml/minute
Air	80 ml/minute.

Injection volume: 10 µl.

Under these conditions Aldicarb sulphone had an approximate retention time of 3.9 minutes.

HRC

APPENDIX 1b

Gas chromatographic conditions used for the determination of amitraz in food

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a nitrogen phosphorus thermionic specific detector and HP 7671A automatic sampler.
Column:	1.8 m x 2 mm i.d. glass packed with 5% OV-101 on Diatomite CLQ (100-120 mesh).
Temperatures:	
Injector	250°C
Column	210°C
Detector	300°C
Gases:	
Carrier	
Nitrogen	35 ml/minute
Flame	
Hydrogen	3 ml/minute
Air	60 ml/minute.
Injection volume:	10 µl.

Under these conditions Amitraz had an approximate retention time of 7.2 minutes.

HRC

APPENDIX 1c

Gas chromatographic conditions used for the determination of endosulphan in food

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a ^{63}Ni electron capture detector and HP 7671A automatic sampler.
Column:	2 m x 4 mm i.d. glass packed with 5% OV-210 on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	300°C
Column	245°C
Detector	350°C
Gases:	
Carrier	
Argon/Methane	40 ml/minute.
Injection volume:	5 µl.

Under these conditions α-endosulphan had an approximate retention time of 4.3 minutes, and β-endosulphan had an approximate retention time of 6.6 minutes.

HRC

APPENDIX 1d

Gas chromatographic conditions used for the determination of organophosphorus compounds (chlorpyriphos, chlorfenvinphos, dimethoate, fenitrothion, profenphos, quinalphos, thiometon, triazophos) in foo

Instrument: Varian Vista 6000 fitted with a flame photometric detector in the phosphorus mode and an autosampler.

Column: 2 m x 2 mm i.d. glass packed with 2½% Apiezon L in Gas Chrom Q (100-120 mesh).

Temperatures:

Injector	225°C
Column	130°C(1 min) —25°/min→ 200°C —3°/min→ 210°C —50°/min→ 270°C(6 min)
Detector	250°C

Gases:

Carrier	
Helium	30 ml/minute
Flame	
Hydrogen	140 ml/minute
Air	170 ml/minute.

Injection volume: 8 µl.

Under these conditions the organophosphorus compounds had the following approximate retention times:

Chlorpyriphos	7.7 minutes
Chlorfenvinphos	8.1 minutes
Dimethoate	4.1 minutes
Fenitrothion	6.8 minutes
Profenphos	9.2 minutes
Quinalphos	8.5 minutes
Thiometon	4.9 minutes
Triazophos	9.7 minutes

HRC

APPENDIX 1e

Gas chromatographic conditions used for the determination of pyrethroids (cypermethrin, decamethrin and fenvalerate) in food

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a ^{63}Ni electron capture detector and HP 7671A automatic sampler.
Column:	1 m x 4 mm i.d. glass packed with 1% OV-101 on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	300°C
Column	215°C(2 min) $\xrightarrow{8°C/min}$ 240°C(4 min)
Detector	300°C
Gases:	
Carrier	
Argon/Methane	60 ml/minute.
Injection volume:	5 µl.

Under these conditions cypermethrin, decamethrin and fenvalerate had approximate retention times of 3.8 minutes, 5.3 minutes and 4.6 minutes respectively.

DEPARTMENT OF ANALYTICAL CHEMISTRY

CERTIFICATE OF ANALYSIS

The Determination of Concentrations of Insecticides

in Water

HTS 3

3rd June 1986

Ian A. Macdonald, L.R.S.C.,
Head of Pesticide and Environmental Analysis,
Department of Analytical Chemistry.

Nigel A. Gillis, B.Sc., G.R.S.C., A.R.C.S.,
Study Analyst,
Department of Analytical Chemistry.

G. A. Taylor.

Graham A. Taylor, B.Sc.,
Study Analyst,
Department of Analytical Chemistry.

A. Eden.

Alan Eden, H.N.C.,
Senior Study Analyst,
Department of Analytical Chemistry.

HRC Project number: HTS 3.

Date of commission: This work was commissioned by Mr. C. R. Whetnall of Hunting Technical Services Ltd on 12th November 1985.

Samples: Samples were received bewteen December 1985 and March 1986 in a good condition and extracted immediately on receipt. Extracts were stored at -20°C prior to quantitation by GLC. Sample W4 was lost in transit prior to receipt by HRC.

Method:

1. Aldicarb

The samples were analysed by shaking with peracetic acid for 2 minutes to oxidise aldicarb to aldicarb sulphone. The mixture was neutralised with 10% aqueous sodium hydrogen carbonate solution and the combined aqueous solution extracted with chloroform. The chloroform was dried through anhydrous sodium sulphate and added to a Florisil clean up column. The aldicarb sulphone was eluted with 5% v/v acetone in diethyl ether and 25% v/v acetone in diethyl ether, the latter fraction being collected, evaporated to dryness and taken up in acetone for analysis by GLC.

Aldicarb sulphone was quantified with a nitrogen phosphorus thermionic detector using the conditions detailed in Appendix 1a.

2. Amitraz, decamethrin, endosulphan and organophosphorus compounds

The samples were analysed by liquid partition from water into dichloromethane. the extract was evaporated to dryness and taken up in 1 : 1 toluene : 2,2,4-trimethylpentane for analysis by GLC.

a) Amitraz was quantified on an OV-101 column with a nitrogen phosphorus thermionic specific detector using the conditions detailed in Appendix 1b.

b) Decamethrin, cypermethrin and fenvalerate were quantified on an OV-101 column with an electron capture detector using the conditions detailed in Appendix 1e.

c) Endosulphan was quantified on a capillary column with an electron capture detector using the conditions detailed in Appendix 1c.

d) Organophosphorus compounds were quantified on an Apiezon L column with a flame photometric detector in the phosphorus mode using conditions detailed in Appendix 1d.

Results:

The results obtained, uncorrected for control or procedural recovery values, are shown in Tables 1-5. Procedural recovery values, corrected for appropriate control residues, are shown in Tables 6-17.

Endosulphan is shown as the total of α and β isomers.

Typical analytical chromatograms are shown in Figures 1-5.

HRC tap water was used as control sample, with no detectable residues being present.

Procedural recoveries were also performed on HRC tap water. Organophosphorus compounds (6 components) were determined simultaneously by GLC. The pyrethroids (3 components) were also determined by GLC. Results are reported as parts per billion (ppb) equivalent to micrograms/litre except for aldicarb, which is reported as parts per million (ppm).

APPENDIX 1a

Gas chromatographic conditions used for the determination of aldicarb in water

Instrument:	Hewlett Packard 5710A series fitted with a nitrogen phosphorus thermionic specific detector and HP 7671A automatic sampler.
Column:	2 m x 4 mm i.d. glass packed with 5% DC-200 and 2% Carbowax on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	200°C
Column	180°C
Detector	250°C
Gases:	
Carrier	
Helium	60 ml/minute
Flame	
Air	80 ml/minute
Hydrogen	3 ml/minute.
Injection volume:	5 µl.

Under these conditions aldicarb sulphone had an approximate retention time of 3.1 minutes.

APPENDIX 1b

Gas chromatographic conditions used for the determination of amitraz in water

Instrument:	Hewlett Packard 5890 gas chromatograph fitted with a nitrogen phosphorus thermionic specific detector and HP 7671A automatic sampler.
Column:	1.8 m x 2 mm i.d. glass packed with 5% OV-101 on Diatomite CLQ (100-120 mesh).
Temperatures:	
Injector	250°C
Column	210°C
Detector	300°C
Gases:	
Carrier	
Nitrogen	35 ml/minute
Flame	
Hydrogen	5 ml/minute
Air	70 ml/minute.
Injection volume:	10 µl.

Under these conditions Amitraz had an approximate retention time of 7.2 minutes.

APPENDIX 1c

Gas chromatographic conditions used for the determination of endosulphan in water

Instrument:		Varian Vista 6000 series fitted with a ^{63}Ni electron capture detector and a Varian 8000 autosampler.
Column:	1.	12 m x 0.22 mm i.d. BP 5 bonded phase capillary column (0.25 µm film)
	2.	12 m x 0.32 mm i.d. BP 5 bonded phase capillary column (0.50 µm film)
Temperatures:		
Injector		250°C
Column		170°C $\xrightarrow{5°/min}$ 250°C (7 min)
Detector		250°C
Gases:		
Carrier		
Helium		3 ml/minute
Make up		
Nitrogen		27 ml/minute
Injection volume:		1.5 µl.

1. Under these conditions α-endosulphan had an approximate retention time of 4.6 minutes and β-endosulphan an approximate retention time of 5.8 minutes.

2. Under these conditions α-endosulphan had an approximate retention time of 8.2 minutes and β-endosulphan an approximate retention time of 10.1 minutes.

APPENDIX 1d

Gas chromatographic conditions used for the determination of organophosphorus compounds (chlorpyriphos, dimethoate, profenphos, quinalphos, thiometon, triazophos) in water

Instrument:	Varian Vista 6000 fitted with a flame photometric detector in the phosphorus mode and a Varian 8000 autosampler.
Column:	2 m x 2 mm i.d. glass packed with 2½% Apiezon L on Gas Chrom Q (100-120 mesh).
Temperatures:	
Injector	225°C
Column	130°C (1 min) —25°/min→ 200°C —8°/min→ 210°C —50°/min→ 270°C (6 min)
Detector	250°C
Gases:	
Carrier	
Helium	30 ml/minute
Flame	
Hydrogen	140 ml/minute
Air	170 ml/minute.
Injection volume:	8 µl

Under these conditions the organophosphorus compounds had the following approximate retention times:

Chlorpyriphos	7.7 minutes
Dimethoate	4.1 minutes
Profenphos	9.2 minutes
Quinalphos	8.5 minutes
Thiometon	4.9 minutes
Triazophos	9.7 minutes

APPENDIX 1e

Gas chromatographic conditions used for the determination of pyrethroids in water

Instrument:	Hewlett Packard 5710A gas chromatograph fitted with a ^{63}Ni electron capture detector and HP 7671A automatic sampler.
Column:	1 m x 4 mm i.d. glass packed with 1% OV-101 on Diatomite CLQ (80-100 mesh).
Temperatures:	
Injector	300°C
Column	215°C (2 mins) ⟶ 8°C/min ⟶ 240°C (4 mins)
Detector	300°C
Gases:	
Carrier	
Argon/Methane	60 ml/minute.
Injection volume:	5 µl.

Under these conditions the pyrethroid compounds had the following approximate retention times:

Cypermethrin	3.8 minutes
Decamethrin	5.3 minutes
Fenvalerate	4.6 minutes
